ABSTRACT

Introduction: Long term complications of *hepatitis C virus* (HCV) infection include fibrosis, cirrhosis, and hepatocellular carcinoma and although the disease is treatable with the newly introduced direct acting antivirals, but factors such as drug resistance, viral genotype and adverse effects can limit the effectiveness of therapy. Therefore, development of effective, safe and affordable prophylactic and therapeutic vaccines is a global goal. This study was undertaken for construction of a vector containing the coding region for a truncated form of nonstructural protein 3 (NS3) of HCV and IL-18 cytokine gene fused to murine Fcy2a as molecular adjuvant for assessment as a DNA vaccine candidate. **Methods:** A truncated form of NS3 was amplified and cloned in pIRES2 containing IL-18 hybrid gene. Expression of the truncated NS3 and bioactivity of IL-18 fusion protein were assessed in transfected HEK293 T cells. Physicochemical properties determination, secondary structure, 3D modeling and T-cell epitope predictions were made using various online tools. **Results:** *In silico* analysis of truncated NS3 predicted a molecular weight of 32.35 kDa containing epitopic regions with the highest scores for binding to MHC complex. 3D model of IL-18 showed that fusion with murine Fc had not impaired the structure. HEK293 T cells were successfully transfected with pIRES-IL18-NS3 construct and expression of truncated NS3 with an apparent molecular weight of approximately 32 kDa was confirmed by Western blotting. **Conclusion:** Despite the advantages, widespread use of DNA vaccination has been hampered by low immunogenicity. Truncated NS3 was expressed albeit in low amount with bioactive IL-18 fusion proteins as a molecular adjuvant. Immunogenicity assessment of this novel combination as a DNA vaccine candidate is underway.

KEYWORDS: HCV, NS3, IL18, DNA vaccine, Adjuvant.

INTRODUCTION

Hepatitis C virus (HCV) is a hepato-tropic member of Flaviviridae viral family with an approximately 9.5 kb positive stranded RNA genome. As has been estimated by the World Health Organization (WHO) 185 million individuals are infected with the virus throughout the world with higher prevalence in the Middle East [1, 2]. The first 6 months of the disease is virtually symptomless and constitutes the acute phase

during which, the virus is cleared in an estimated 20-30% of the Infected without any therapy, whereas in the remaining 70-80% of newly infected, the disease becomes chronic with long-term complications including fibrosis, cirrhosis, and hepatocellular carcinoma [3]. Although HCV infection can be treated with the newly introduced direct acting antivirals, but factors such as drug resistance, viral genotype, host factors, cost, access, efficacy and adverse effects can limit the effectiveness of therapy. Therefore, development of effective, safe and affordable prophylactic and therapeutic vaccines against HCV infection remains a global goal. Although induction of immunity after spontaneous viral clearance in primary HCV infection suggests that development of an effective vaccine is possible, but despite all efforts no such vaccine has been developed yet [4]. There is ample clinical evidence showing a major role for both CD4+ and CD8+ T cells in clearing primary and secondary HCV infections particularly the CD4+ immune

responses to non-structural protein 3 (NS3) in acute phase clearance [5]. NS3 is a 69 kDa multi-functional hydrophobic protein with serine protease and nucleoside triphosphatase (NTPase)/RNA helicase activities involved in processing of the viral polyprotein and viral RNA replication. It has been shown that NS3 induces immune responses capable of clearing HCV, making it an attractive candidate for a therapeutic vaccine [5-8]. DNA vaccination technology is a promising platform offering a number of advantages over traditional immunization such as safety and cost, but the main advantage of this vaccine modality is the ability of DNA vaccines to stimulate both arms of adaptive immune system, eliciting strong CLT and B-cell immunity [5]. However, despite all the advantages, DNA vaccines have not had widespread usage and the major impediment to their use has been their low immunogenicity in humans [5]. One of the strategies used for overcoming this obstacle has been the co-administration of immunomodulatory cytokines such as IL-18. Transfected cells can express the molecular adjuvant which can modify the immune response towards each particular pathogen [9]. IL-18 is expressed as a 24 kDa inactive pro-IL-18 requiring conversion to a secreted 18 kDa active protein by enzymatic digestion with cysteine caspase-1 [10]. Recently it has been shown that priming of natural killer lymphocytes with IL-18 results in memory-like properties and enhanced IFN- γ production [11]. Cloning the sequence for mature IL-18 renders the polypeptide non-secretory necessitating introduction of a signal sequence for the expressed protein to be secreted. Therefore in this study a previously constructed vector containing mature IL-18 fused to the signal sequence of immunoglobulin kappa (IgK), and mice IgG1 Fc fragment (murine Fcy2a) was used [12] for cloning of a truncated form of NS3 for assessment as a DNA vaccine candidate.

MATERIALS and METHODS

PCR primers were synthesized by Pishgam Biotech (Iran). All enzymes and other routine molecular biology reagents were purchased from Thermo Scientific (Germany). RNA extraction, plasmid purification and cDNA synthesis kits were from Qiagen (Valencia, CA).

Bioinformatics analysis of NS3 and IL18 fragments

In this study, protein sequences of NS3, mature IL-18 and murine Fcy2a fragment were derived from national center for biotechnology information (<http://www.ncbi.nlm.nih.gov>). Physicochemical properties of the proteins were computed using ProtParam online tool (<http://web.expasy.org/protparam/>) [13].

Self-optimized prediction method with alignment (SOPMA) (http://npsa-pbil.ibcp.fr/cgi-bin/npsa_automat.pl?page=/NPSA/npsa_sopma.html) was used for secondary structure prediction of IL18 and mice IgG1 FC fragment (murine Fcy2a) fusion protein and for calculating the number of α -helix, β sheets, turns random coils, and extended strands [14]. The 3D model was obtained using the Threading Assembly Refinement (I-TASSER) online server program which generates 3D models along with their confidence score (C-Score). Calculation of this score which is an evaluation of the quality of the predicted model is based on the significance of threading template alignments and the convergence parameters of the structure assembly simulations [15]. Stereo chemical analysis of obtained 3D protein models were performed using PROCHECK, ERRAT, VERIFY 3D programs for structural analysis which were verified using

SAVES server (<http://nihserver.mbi.ucla.edu/SAVES> and RAM-PAGE) [16-19].

SMART (Simple Modular Architecture Research Tool, <http://smart.embl.de/>) online software and InterPro database (protein sequence analysis & classification, <http://www.ebi.ac.uk/interpro/>) were used for IL-18 fusion protein domain prediction [20-21].

T-cell epitope regions of NS3 protein were predicted using the web servers SYFPEITHI (<http://www.syfpeithi.de/>) and ProPred-I (<http://www.imtech.res.in/raghava/propred1/>) [22-23]. The results obtained showed a sorted list of nine amino acid substrings of the submitted antigen sequence for affinity calculations.

Construction of the expression vector

Plasma from a confirmed, chronically infected HCV-1 patient was used for amplification of NS3 fragment. Total RNA extraction and cDNA synthesis were performed as previously described [12] and the 927bpNS3 fragment was amplified using F-NS3: 5'-CTG CAG ATC CAC AAC CAT GGG TCC TGT CAT CC-3' and R-NS3: 5'-ATA GTT TAG CGG CCG CTC AGA GCT CGT CGC A-3' as forward and reverse primers respectively. Pfu DNA polymerase was used in 35 cycle amplification with initial denaturation at 94 °C for 5min followed by denaturation at 95 °C for 30s, annealing at 52 °C for 30 s, elongation at 72 °C for 60 s, and the program ended with a final extension at 72 °C for 10 min.

Amplified product was digested with BstXI and NotI and cloned in similarly digested pIRES2 (Clontech, USA) replacing the sequence for EGF protein in the vector. The construct was transformed into competent *E. coli* DH5 α and transformants were selected on Luria Bertani (LB) agar plates containing 50 μ g/ml kanamycin (Sigma-Aldrich, USA). The authenticity of the cloned gene was verified by sequencing (SEQLAB, Germany). Construction and cloning of IL-18 fusion protein in pIRES2 vector have been described previously [12].

Expression of NS3 protein in eukaryotic cells

Human HEK293T cells were grown and maintained in DMEM medium containing 2 mM L-glutamine, 100 U/ml penicillin, 100 mg/ml streptomycin (Biosera, France), supplemented with 15% fetal calf serum (Invitrogen, USA), at 37 °C under humidified air containing 5% CO $_2$ with a daily change of culture medium for 4 days. Plates were seeded with 2.4 x 10 5 cells, grown to 70% confluency and transfected with 100 ng of pIRES2-EGFP and pIRES-IL18-NS3 using TurboFect *in vitro* Transfection Reagent according to the manufacturer's protocol (Thermo Scientific, USA). After 60 h, cells were washed with phosphate-buffered saline (PBS, pH~7.5) and transfection efficiency was analyzed by fluorescent microscopy and SDS-PAEG showing expression of EGFP reporter and NS3 respectively.

Western Blot analysis

Transfected HEK-293 cells expressing NS3 and untransfected cells (negative control) were washed three times with PBS and lysed with buffer containing 0.5 mM EDTA, 1 mM DTT, 2 mM sodium fluoride, 10% glycerol, 0.2% Triton X-100 in PBS pH 7.4 and protease inhibitors (Calbiochem France). Proteins electrophoresed on 12% polyacrylamide-SDS gels and separated protein bands were transferred to PVDF membranes (Pall, USA) using semi-dry blotting system (Bio-Rad, USA). Membranes were blocked with BSA (3%) at room temperature for 2 h and incubated with 1:100 dilution of mouse anti-NS3 monoclonal antibodies (Abcam, USA) for 1 h. Subsequently, washed membranes were incubated with 1:1000 dilution of

HRP- conjugated rabbit anti-mouse IgG/HPR (Sigma–Aldrich, USA) as secondary antibody and developed using 3,3'-diaminobenzidine (DAB, Bio-Rad USA).

Expression and bioactivity of recombinant murine IL-18

Expression and biological activity of recombinant IL-18 fusion protein in the concentrated cell supernatants of HEK-293 T cells was measured using IL-18 ELISA kit (Bender MedSystems, Austria) and Mouse IFN- γ ELISA (U-cytech bioscience, Netherlands) according to manufacturer's instructions as previously described [12].

Fig. 1. Schematic presentation of recombinant pIRES-IL18-NS3.

RESULTS

The primers designed in this study successfully amplified the selected NS3 gene fragment and the authenticity of the product was verified by sequencing. The coding sequence for full-length NS3 starts from 3623 nucleotide to 4550 of HCV subtype 1 complete genome corresponding to amino acids 1027 to 1658 of its polyprotein consensus sequence (NCBI accession number AF009606). The amplified fragment consisted of 120 aa of NS3 N-terminal portion and 189 aa were from domain 1 of NS3 helicase.

In silico evaluation of the 310 amino acids of truncated NS3 fragment showed that there are a large number of hot spot regions in this fragment that can be recognized by MHC class 1. Consensus T cell epitopes predicted by both SYFPEITHI and ProPred-I methods were combined to achieve a credible T cell epitopes prediction for full-length and truncated NS3. The epitopes from the target region of NS3 protein using SYFPEITHI listed in Table 1 showed the highest score.

Analysis of the physicochemical parameters of this fragment using ProtParam online tool calculated an isoelectric point (pI) of 8.34 and a grand average hydropathicity of 0.051 with an apparent molecular weight of 32.35 kDa.

IL-18 fusion protein consisted of 392 amino acids and physicochemical characterization of the protein estimated a molecular weight of 44.5557 kDa and a theoretical isoelectric point of 5.72 with the calculated grand average hydropathicity of -0.484. The total number of positively (Arg+ Lys) and of negatively charged residues (Asp+ Glu) in the polypeptide was 45 and 54 respectively.

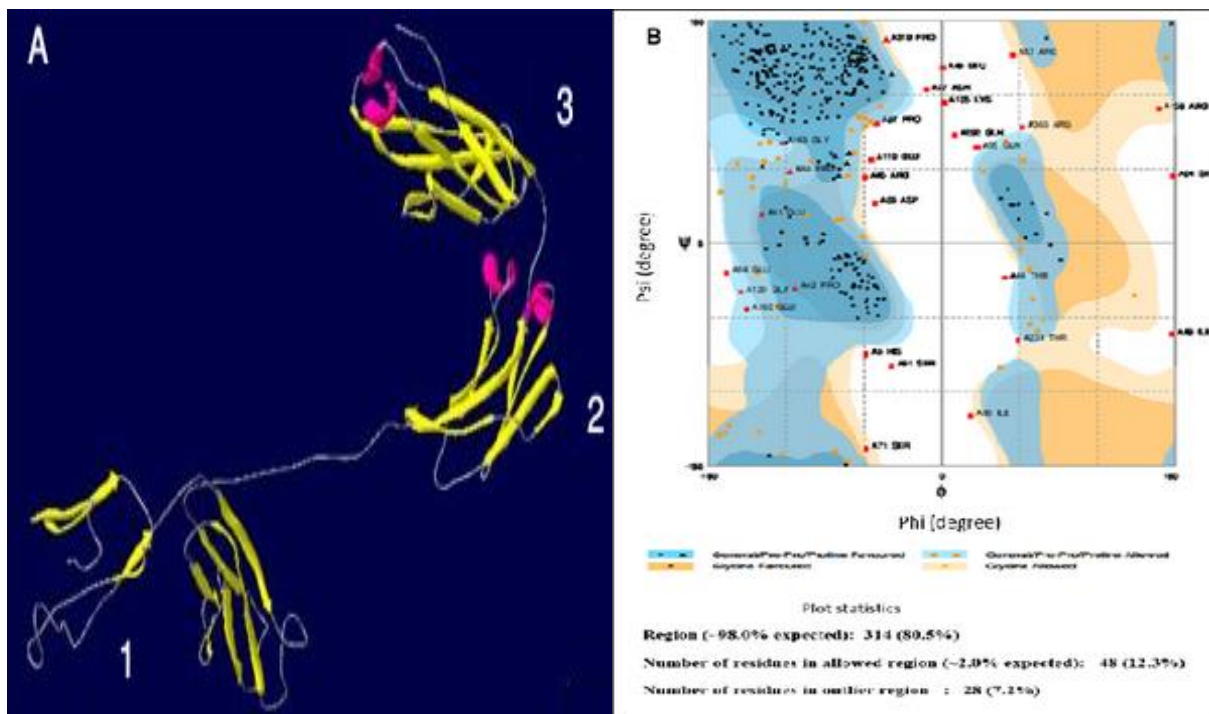

Fig. 2: 3D model of IL-18-murine Fc γ 2 a fusion protein. A- Predicted 3D model of IL-18-murine Fc γ 2 a fusion protein obtained from I-TASSER. Image was produced using the Swiss PDB viewer with colors identification as; helices, pink; beta sheets yellow; and all others gray, aa 14-132, IL-1 domain 1, aa 201-276, IG-like domain 2, aa 307-380, IGc1 domain 3 [24]. B- Ramachandran plot of IL18 fusion protein predicted by RAMPAGE, showing residues in favored, allowed outlier regions.

3D structure of the IL-18 fusion protein was predicted using the I-TASSER online server and the best predicted structure with the maximum confidence score (C-Score -0.44) was selected (Fig. 2A). The predicted 3D model showed that the cytokine had 3 well defined domains and fusion with murine Fc to the C-terminal had not impaired the structure. Ramachandran plot for the model showed 80.5% of the protein residues in the favored, 12.3 % residues in allowed and 7.2% residues in outlier regions (Fig. 2B).

Expression and bioactivity of IL-18

Expression of IL-18-murine Fc₂ fusion protein was assayed and the amount of the expressed protein was estimated as 250 pg/ml with bioactivity of approximately 27 pg/ml similar to previously reported data [12]. Detection of IL-18 and its bioactivity in the HEK293T cell culture was taken as evidence of IL-18 secretion.

NS3 expression on eukaryote cells

Analysis of the transfected cells lysate by SDS-PAGE and subsequent Western blotting confirmed low expression of NS3

protein by HEK293T cells (Fig.3A). Apparent molecular weight of the expressed protein was approximately 32kDa, similar to that calculated by ProtParam online tool.

Expression of the protein was confirmed by Western blotting with mouse anti-NS3 monoclonal antibody (Fig. 3D).

DISCUSSION

Spontaneous clearance of HCV in a small portion of the infected hosts has spurred the search for prophylactic and therapeutic vaccines against this viral infection. NS3 protein is one of the more genetically conserved antigens in the highly variable HCV genome and the importance of its specific T cell responses in clearance of acute infection has been shown [25]. The protease and helicase activities of the protein have been mapped to the N-terminal one third and C-terminal two thirds of the full-length polypeptide respectively [26]. The enzymatic activities of NS3 while pivotal in viral lifecycle may

interfere with host defense mechanism, therefore in this study a truncated form of the protein lacking protease and helicase activity was used [7]. Truncated fragment however, contained a number of T cell epitopes that ranked very high in *in silico* analysis (Table 1). Comparison of epitopic regions in full-length NS3 with the truncated form showed that epitopic domains with the highest score in full-length protein were located in the truncated NS3. Expression level of the ΔNS3 was not very high despite the reduction of cysteine residues from 20 in to 9 (Fig. 3) which was similar to the result reported by Hosseini *et al.* [27].

Calculated grand average hydropathicity of the selected segment was slightly higher compared to the full form which could have adversely affected the expression level of the heterologous protein. Recent studies have shown that the presence of the NS4A cofactor improves expression and immunogenicity of the expressed protein and the higher immunogenicity was attributed to the higher expression of NS3[28]. Therefore increasing the expression level of the truncated NS3 requires production-enhancing strategies which are underway to improve the suitability of the proposed candidate antigen. However, preliminary data obtained have indicated that the combination of truncated NS3 and IL-18 used in this study is capable of stimulating an adequate immunological response and the immune response is protective (data not shown).

The multifunctional IL-18 cytokine strongly stimulates innate and adaptive immune systems, boosting Ag-specific T cell responses and can be used as an effective adjuvant in DNA vaccination [9]. Fusion of murine Fcγ2a fragment added nearly 26 kDa to molecular weight of IL-18 and reduced the grand average hydropathicity of the protein slightly. Several advantages have been cited for fusion of murine Fcγ2a to cytokines including increased avidity, prolonged circulating half-life due to molecular size increase and reduced renal clearance. Furthermore, fusion with Fc results in alteration of complement-mediated and antibody dependent cell-mediated cytotoxicity, enhancing the effects of IL-18 as a molecular adjuvant [29]. The strong stimulatory effect exerted by IL-18 fusion protein might compensate for the low expression level observed for the candidate antigen.

In conclusion the combined use of truncated NS3 and IL-18 has the potential to be used as candidate therapeutic DNA vaccine.

ACKNOWLEDGEMENT

We thank A. Memarnejadian, S.M.Sadat and R.Vahabpour for their kind help and generous advice. This research was supported by grant no.478 from Pasteur institute of Iran.

CONFLICT OF INTEREST

The authors declare that they have no conflict of interest.
